# NASSELLA AND OR YZOPSIS (POACEAE) IN NEW SOUTH WALES 

Joyce W. Vickery† and S. W. L. Jacobs

(Accepted for publication 14.3.1980)

#### Abstract

Vickery, Joyce W'. and S. W. L. Jacobs (Roval Botanic Gardens, Sydney, Australia) 1980. Nassella and Oryzopsis (Poaceac) in New Somh Wales. Teloped 2 (1): 17-23.-The generic placement of Nassella michotama is discussed, particularly in relation to Stipa. A synoptic key is presented to distinguish the closely related genera throughout the world and a key included to distinguish the genera in New South Wales, followed by a taxonomic treatmen for Now South Wales of Nassella and Oryzopsis and a note on Piptochactium.

## INTRODUCTION

The gencra Stipa, Oryzopsis, Piptochaetinm and Nassella form a group of closely related genera in the tribe Stipcac (Clifford \& Watson 1977). Stipa is a large genus with probably over 300 species in the temperate, rarely tropical, regions of the world, Oryzopsis a genus of about 24 species in the temperate and subtropical regions of the northern hemisphere, Nassella a South American genus of about 10 species and Piptochactium a temperate South American genus of about 20 species. Although the generie limits within the group have always been somewhat ill-defined and there have been transfers from one genus to another, the genera Oryzopsis and Piprochaetium scem to be aceepted by recent workers with little disagreement, (e.g., Rosengurtt et al. 1970: Gould 1975): the distinguishing characters are given in the key below. There is some disagreement about the generic distinetions between the genera Stipa and Nassella; N. trichotoma being one of the central species in the problem. Stipa is a very large and cosmopolitan genus whose limits are indeed difficult to define, especially in South Amcrica.
N. trichotoma certainly does not belong to either of the genera Oryzopsis or Piplochactillu, from both of which it differs in its very asymmetric gibbous Iemma with tardily deciduous excentric avn, and from Piptochaetimm it differs further in its nerveless palea shorter than the lemma and the lack of a corona on the lemma.

## Generic placement of Nassella trichotoma

Some South American authors, such as Parodi (1944, 1947), Duren \& Rosengurtt (1956) and Caro (1966) have rejected N. trichotoma from the South American genus Nassella and treated it (sometimes tentatively) as a species of Stipa. However, N. trichotoma would be a very aberrant species of Stipa, if placed in that genus, whereas it has many strong resemblances to other species of Nassella (cf. Parodi 1947). Its difference from the majority of species of Stipa was recognized by Corti (1951, sce Caro 1966), who created the separate section Nassellopsis in Stipa in order to accommodate it.

Parodi (1947) lists laterally compressed spikelets, overlapping Iemma margins, rudimentary paleas, casily deciduous awns, several-noded culms and sheaths shorter than the internodes as characteristics of Nassella. N. trichotoma differs in having few-noded culms and, supposedly, sheaths longer than the internodes. The immature infloreseenec of $N$. trichotoma (the ones usually present on herbarium specimens) do have the sheaths longer than the internodes but on mature panicles the sheaths are shorter than the upper internodes. N. trichotoma has few (2-4) noded culms but Parodi describes $N$. pubiflora with 2-4 nodes and $N$. fuscescens with 3-5 nodes.

In tentatively excluding N. trichotoma from Nassella, Parodi also lists the persistent awn and long setaccous leaves as being not characteristic of Nassella and suggests they are more characteristic of Stipa. The awn of $N$. trichotoma is perhaps more tardily deeiduous than the awns of some other species of Nassella but it is still readily deciduous and quite different from the awns of at least the Australian species of Stipa. Long setaceous leaves do appear to be uncommon in Nassella but N. juncea is deseribed as having "juneiform" convolute leaves, up to 8 cm long and 1.5 mm wide; shorter than but not dissimilar to the leaves of $N$. trichotoma.

## N. trichotoma clearly falls within the concept of Nassella as expressed by Henrard

 (1929) in his key to the genera of the Stipeac.Although desirable, it is not always necessary to have absolute character discontinuity before a genus can be segregated, and it is important to look at the assemblages of characters as well as the individual characters. In this particular example, we consider that the eharacteristies $N$. trichotoma shares with other specics of Nassella are more important than the differences, which appear to be specialized trends with intermediate states in other species of Nassella. Our reasons for retaining N. trichotoma in Nassella may be assessed from the following comparative summary (Table 1) of some characters of the two genera and of $N$. trichotoma.

## Synoptic Key to the genera Stipa, Nassella, Oryzopsis and Piptochactium

1. Lemma usually several times longer than broad, cylindrical, fusiform, pyriform or turbinate, rarely slightly gibbous, tapering at the tip or rarely slightly 2 -lobed, convolute and totally enclosing the palea. Aw $h$ from the apex of the lemma or from between its lobes, $\pm$ persistent or tardily deciduous, twisted in the lower part, generally onee or twice geniculate. Callus longer than the width of the lemma, very oblique, sharp-pointed and bearded, rarely obtuse. Corona present or absent. Palca byaline, 2 -nerved and 1 -keeled, flat or rudimentary or absent. Lodicules 3, rarcly 2, hyaline, elongate, tapering to an obtuse tip. Sfaments 3 , the anthers often hairy at the tips. Grain fusiform-terete. Ililum linear, nearly as long as the grain. Embryo basal, about one-fifth the length of the grain . . . . . . . . . . . . . . . . . . . . Stipa
1.* Lemma short and broad, or sometimes narrow and eylindrical in Piptochetimm but then not fully enelosing the palea and a corona usually present. Awh slender, deciduous. ........ 2 .
2. Lenma elliptical-oblong or fusiform or ovate, not gibbous at the top. Awn terminal and central from the minutely lobed apex, straight, very readily deeiduous. Corona reduced or absent. Callus short and obtuse. Palea shorter than to subequal to the lemma, embraced by but not totally enclosed by its margins, 2 -nerved. Grain readily separable from lemma and palca, oblong, sub-terete. Stameus 3. Lodicules 2, rarcly 3, hyaline. . . . . . . Oryzopsis
2.* Lemua asymmetric, gibbous at the summit, obliquely obovate, or narrow and cylindrical in species of Piptochaction but then with a distinet corona. dwn exeentrically attached, readily deciduous.
3. Palea short, hyaline, without nerves or keels. Lemma obliquely obovate, asymmetric, gibbous at the summit, entirely enelosing the palea, rigid. Corona absent. Callus short, not as long as the width of the lemma, not strongly oblique, not long-pointed. Lodicules 2, obtriangular, truncate.

Nasselía
3.* Palca rigid, crustaceous or coriaccous, 2-keeled with a median furrow between the kecls, exposed between the margins of the lemma and the tip projecting beyond the lemma. Lemmo obliquely obovate or pyriform, asymmetrie and gibbous or cylindrical and not conspicuously gibbous, the apex acute or obtuse, not enclosing the palea and having a suleus on the palca side. Corona usually present. Awn persistent or caducous, centric or excentric, often bigenieulate. Lodicules 3, lanceolate.

Pipfochactium

## Key to Stipa, Nassella and Oryzopsis in New South Wales

1. Awn excentric, readily to tardily deeiduous. Inflorescence disarticulating as a unit, old infloreseenee stalks not left on plant.

Nassella
1.* Awn terminal and central, persistent or deciduous. Spikelets disarticulating individually from the inflorescence and old inllorescence stalks persistent.
2. Lemma ovoid with a terminal deciduous awn; callus shorter than the widtin of the lemma. Oryzopsis
2.* Lemma cylindrical, rarely gibbous, with a terminal persistent awn; eallus usually longer than the width of the lemma.

Stipa

TABLE 1.
Summary of characters of Stipa, Nassella and Nassella trichotoma

| Character | Nassella | N. trichotoma | Stipa |
| :---: | :---: | :---: | :---: |
| Culms | slender to firm, usually not persistent. | very slender to eapillary, absent from old tussocks. | firm, persistent and recognizable in old tussocks. |
| Panicle | persistent or deciduous. | deciduous and usually removed before the florets have fallen from the glumes. | persistent, with the florets falling in sifu from the glumes. |
| Spikelets | rather small. | rather small. | large to rather small. |
| Lemma | ovoid or asymmetrically elliptical, not more than twice as long as broad, $1-3 \mathrm{~mm}$ long, usually more or less strongly gibbous, without a corona. | ovoid, asymmetrical, very strongly gibbous, without a corona, 2 mm long and 1 mm wide. | cylindrical or narrowly very several times as long as broad, more than 3 mm long including the callus, not or only slightly gibbous, with or without a corona. |
| Awn | cxcentric, filiform, straight or flexuose, slightly twisted in the lower part, glabrous, inconspicuously articulate and tardily to readily deciduous. | excentric, filiform, straight or flexuose, only slightly twisted in the lower part, glabrous, inconspicuously articulate and tardily deciduous. | terminal and centric, usually rather strong manifestly articulate with the lemma, persistent or tardily deciduous, usually differentiated into a morc or less strongly twisted column and a straight or curved bristle, often geniculate, glabrous, plumose or variously hairy seabrous. |
| Callus | short (shorter than the diameter of the lemma), slightly oblique, obtusc or minutely acute. | short (shorter than the diameter of the lemma), obtuse or minutely acute, very slightly oblique. | long (longer than the diameter of the lemma), very oblique, usually pungent-pointcd (? rarely obtuse). |
| Palea | nerveless. | nerveless. | 2-nerved, rarely rudimentary or absent. |
| Lodicules | 2, obtriangular, truncate. | 2, obtriangular, truncate. | usually 3 , rarcly 2 , elongate, tapering to an obtuse point. |
| Stamens | 3, without a hairy tip. | 2 (or 3 ) with only 1 anther fully developed and 1 (or 2) staminodes, without a hairy tip. | 3 , the anthers often hairy at the tips. |
| Grain | oblong to obliquely pyriform, slightly compressed. | obovoid (pyriform) and slightly compressed. | fusiform-terete. |
| Embryo | one-third to one-half the length of the grain. | almost one-half the length of the grain. | about one-fifth the length of the grain. |
| Hilum | linear and about twothirds the length of the grain. | linear and about twothirds the length of the grain. | linear, nearly as long as the grain. |

# TAXONOMIC TREATMENT OF ORYZOPSIS AND NASSELLA AND A NOTE ON PIPTOCHAETIUM 

ORYZOPSIS Michx.
Spikelets solitary, pedicellate, hermaphrodite, I-flowered with the fioret disarticulating above the glumes and the rhachilla not produced beyond the floret, bornc in open or more or less contracted panicles. Ghmes equal or slightly unequal, obtuse to acute or acuminate, membranous to firm, usually 3- to 5-nerved. Lemma shorter than to about as long as the glumes, rigidly membranous to coriaceous or indurate, oval, oblong, lanceolate, ovate-lanceolate or obovate in outline, convolute, appressed-pubescent to glabrous, 3- to 5 -nerved, with a short, blunt, oblique callus, terminally or subterminally awned with the awn deeiduous, slender, glabrous, straight or more or less geniculate. Palea shorter than to subequalling the lemma and embraced by its margins, 2 -nerved. Stamens 3. Lodicules 2, rarely 3, hyaline, rather large. Ovary glabrous; styles free, short; stigmas plumose, laterally exserted. Grain oblong, oval or obovate in outline, terete, tightly enelosed by the hardened lemma and palea. Caespitose peremials. Sheatlis open. Ligules membranous, truncate to elongate. Blades flat to involute.

A genus of about 24 species mostly native to the temperate and subtropical regions of the northern hemisphere. One naturalized in Australia.
*O. miliacea (L.) Aschers. et Schweinf., Mém. Inst. Égypte 2: 169 (1887); Summers in J. Dept. Agric. South Australia 10: 418, phot. (1907); J. M. Black, Naturalized FI. Sydney Region: 657 (1972).

Synonymy: Agrostis miliacea L., Sp. Pl. I: 61 (1753). Piptatherum miliaceun (L.) Coss., Nol. Cril.: 120 (1851).

Milium unltiflorum Cav., PI. Deser.: 36 (1802). Piptathermu unhltiflorum (Cav.) Beauv., Agrost.: 18, 168, 173 (1812).

Milium thomasii Duby in Candolle, Bot. Gall. I: 505 (1828). Piptathertum thomasii (Duby) Kunıh, Rev. Graminées I Suppl.: XIV (1830).

Distribution: North and Central Coast, Northern and Central Tablelands, Central and South Western Slopes, Western and Far Western Plains, usually in situations sheltered from grazing by stock. Also in Vietoria, Tasmania, South Australia and Western Australia; used to stabilise minc-dumps in moist and semi-arid regions in the soumern half of Australia and frequently spreading from such plantings. Native to the Mediterrancan region; introdueed into Australia and North America.

Tufted perennial with a strong contracted rhizome with extravaginal innovations, glabrous except for the pubeseent eataphylls. Culms slender to rather stout, rigid, wiry, leafy, branching and often with fascieles of branches at the nodes, ereet, $60-150 \mathrm{~cm}$ long, subsmooth, 6- to 7 -noded. Sheaths usually shorter than the internodes, tight around the culm, smooth, striate. Ligule hyaline, very obtuse or truncate, 2-3 mm long. Blades flat, $7-35 \mathrm{~cm}$ long, $8-10 \mathrm{~mm}$ wide, linear, finely long-acuminate, slightly seabrous above, smooth and often almost shining below, the midrib somewhat prominent below. Panicle 15-40 cm long, loose, open, the numerous, capillary, scabrous branches verticillate at the nodes, spreading and somewhat drooping towards their tips, branehing to the sceond or third degree, bearing numerous, small, shortly pedicellate spikelets above the middle. Spikelets lanceolate, $3-3.5 \mathrm{~mm}$ long, greenish to purplish. Ghumes membranous to hyaline, as long as the spikelet, long-acuminate, slightly unequal, pale greenish to purplish. Lemma $1.8-2 \mathrm{~mm}$ long, ovoid, shortly
notched at the summit, smooth, glabrous, hardened around the fruit and shining at maturity, bearing a terminal, readily deciduous, straight, capillary awn $2-4 \mathrm{~mm}$ long. Palea as long as the lemma, 2-nerved. Anthers c. 1 mm long. Caryopsis oblong, subterctc. "Riec Millet", "Many-flowered Millct Grass", the "Smilo Grass" of the U.S.A.

Specimens Examined: North Coast: Wollongbar Experimental Farm, cult., NSIW 115744, 12.1903. Central Coast: Botanic Gardens, Sydney, cult., Boorman NSW 115749, 5.1905; Homebush, Vickery' NSW 17931, 11.1932; Hawkesbury Agricultural College, Richmond, eult., NSW 115758, 3.1909, The Principal NSW 115761, 11.1908. Northern Tablelands: Armidale. Vane NSW 115735, 1.1965. Central Tablelands: Orange district, Madsen NSW 115752, 12.1950; Bathurst Experiment Farm, NSW 115746, 3.1903. Southern Tablelands: Black Mtin, Canberra (A.C.T.), Gray 5788, 11.1965 (115737). Central Western Slopes: Cassilis, Hemry NSW 115755, 5.1931; Boree Creek, Cornell NSW' 115736, 11.1938; Cowra, Brown NSW 115741, 7.1961, McBarron 9158, 8.1964 (NSW); Young, cult., Thomber NSW 115760, 2.1908; Young, NSW 115747, 1933. South Western Slopes: Murrumburrah, Morgall NSW 115748, 12.1940; Springfield, North Wagga, Commins NSW 115754, 1.1934; Wagga Wagga, Stening NSW' 115756, 10.1913, Hutclinson NSW 115751, 3.1972: Wagga Experimental Farm, The Manager NSW 115753,9.1904; Wagga Wagga Soil Conservation Researeh Station, NSW 115763. 1955; Albury, Yates \& Co. NSW I15745, 3.1913, McBarron 1392, 2.1948 (NSW). Western Plains: Leeton distriet, Watkins NSW II5743, 11.1950. Far Western Plains: Broken Hill, Morris NSW 115742, 3.1921 .

A drought resistant grass of which the young foliage is palatable to stock but the mature tussocks with their wiry stems are not. Its virtual restrictions to sites sheltered from stock, such as gardens and waste land in country townships, indicates that it docs not withstand grazing. It is somewhat dceorative.
O. hymenoides (Roem. \& Schult.) Ricker has been cultivated experimentally by the CSIRO at Ginninderra, Canberra (A.C.T.) [Strong NSW 115733, 11.1962].

## NASSELLA E. Desv.

Spikelcts all alike, hermaphrodite, 1-flowered with the rhachilla not prolonged beyond the floret. Glumes 3-ncrved, lanceolate, acuminate, longer than the floret, subequal, persistent, with the lower back more or less herbaceous and greenish or purplish, the margins and apices scarious or hyaline. Florct obovate, obliqucly pyriform, oblong or lanceolate, gibbous, slightly laterally compressed, without a corona, 1-3 mm long, with an excentric awn. Lemma cartilaginous and rigid or papery, glabrous or pubescent, the margins strongly overlapping and completely conecaling the palea and flower, the callus very slightly and shortly oblique, obtuse or very shortly acute, glabrous or pilose, the awn slightly and loosely twisted or slightly geniculate or flexuosc, deciduous, $1-3 \mathrm{~cm}$ long. Palea $1-n c r v e d$ or nerveless, much shorter than the lemma, often hyaline, included within the lemma. Stamens 3 , sometimes 1 or 2 of them reduced to staminodes or absent. Ovary oblong or fusiform with short styles and short, lightly plumose stigmas. Caryopsis oblong to obliquely pyriform or obovoid, very slightly compressed, the hilum linear. Pcremials, usually with several-noded, usually branching, culms or these simple with inconspicuous nodes and short internodes at the base of the clongate peduncle, in the former case the sheaths usually shorter than the internodes. Ligules short. Blades flat or involute, acuminatc. Inflorescence a contracted or open panicle.

A South American genus of about 10 species chicfly in or near the Andes extending from Ecuador southwards to lat. $42^{3}$ in Patagonia. One species naturalized in Australia, New Zcaland and the United States.
*N. trichotoma (Nees) Hack. ex Arech., Anales Mus. Nac. Montevidco 1: 336, fig. 19 (1896); Cross, Agric. Gaz. New South Wales 48: 546-548, figured (1937); Allan, New Zcaland J. Agric. 63: 91-95 (1941); Cross \& Vickery, Contr. New South Walcs Natl. Herb. 1: 278 (1950); Blakclow, Tasmanian J. Agric. 31: 458-464, figured (1960); Campbell, Agric. Gaz. New South Wales 71: 9-19, figured, and 561
(1960) and ibid. 76: 679-687, figured (1965); J. H. Willis, Handb. Pl. Victoria 1: 188 (1962) and edn 2: 188 (1970); Goodyear, J. Agric. (Melbourne) 62: 314-317, figured (1964); Whittet, Weeds edn 2: 361-363, phot. (1968); Burbidge \& Gray, Fl. Austral. Cap. Terr.: 54, fig. 46 (1970). Extensively mentioned in the Agricultural literature of eastern Australia and New Zealand since 1937.

Synonymy: Stipa trichotoma Nees, Agrost. Bras.: 375 (1829); Parodi, Revista Muse de la Plata, Secc. Bot. 6: 306 (1944); Parodi, Darwiniana 7: 369 (1947); Durán \& Rosengurtt, Agros (Montevideo) No. 141: 12 (1956); Caro, Kurtziana 3: 79 (1966). Urachne trichotoma (Nees) Trin., Mem. Acad. St. Pétersb. ser. 6, Sci. Nat. 1: 124 (1834). Piptochaetium trichotoma (Nees) Griseb., Symb. FI. Arg.: 297 (1879).

Distribution: Naturalized and widely distributed on the Central and Southern Tablelands, more infrequently extending to the Northern Tablelands, Central Western Slopes and South Coast; also in Victoria and Tasmania. Native to South America; introduced into Australia and New Zealand.

Densely caespitose peremial with very numerous, often sterile, intravaginal innovations and wiry roots, the tussocks $20-60 \mathrm{~cm}$ high. Culms 2 - to 4 -noded but the nodes not thickened, quite inconspicuous and chiefly towards the base, very slender to almost capillary and each internode becoming attenuate downwards, simple, terete, smooth, glabrous. Sheaths tight around the culms or open towards the base of the plant, lightly striate, glabrous and smooth cxcept for the more or less scaberulous margins, erect. Ligule opaque-whitish, papery, obtuse or truncate, $0.5-2.5 \mathrm{~mm}$ long, glabrous and smooth or more or less scaberulous on the back, symmetrical or asymmetrical and sublateral. Blades straight or curving outwards in the upper one-third, convolute-filiform, setaceous, c. $15-45 \mathrm{~cm}$ long, $0.25-0.5 \mathrm{~mm}$ in diameter, finely but not pungently pointed, the exterior surface minutely and rather distantly scaberulous, not striate with nerves, the interior surface scaberulous, fewnerved and furrowed between the nerves. Panicle at first more or less included in the uppermost sheath and then contracted, at length shortly exserted, pyramidal, very effuse with rather few spikelets towards the tips of the ultimate branches, erect, $15-25 \mathrm{~cm}$ long, often purplish from the colour of the glumes, the main axis somewhat compressed and planoconvex, antrorsely scabrous on the edges, the filiform branches 2 - to 3 -nate, scabrous-pubescent, the lower up to 10 cm long, again unequally branched and the spikelets borne on the ultimate branchlets on long capillary pedicels compressed upwards and only slightly thickened at their tips. Spikelets narrowly lanceolate. Glumes much longer than the floret, narrowly lanceolate, finely longacuminate into a hair-like tip, the lower part of the back membranous and usually purplish, the margins upwards and the apex thinly hyaline, 3-nerved with the lateral nerves shorter and converging towards the median nerve, subsmooth, loose around the floret, somewhat unequal with the lower glume $6-8.5 \mathrm{~mm}$ long and c. 1.5 mm wide, slightly scabrous on the lower part of one margin, the upper glume $5-7 \mathrm{~mm}$ long and almost as wide as the lower. Floret obovate, very gibbous on the back, slightly compressed, without a corona, $1.5-2 \mathrm{~mm}$ long (without the awn), c. 1 mm wide. Lemma obscurely (at least on the outer surface) 5 -nerved, strongly antrorsely scabrous upwards, otherwise glabrous, straw-coloured or somewhat purplish, with a very excentric filiform awn, the margins overlapping and tightly enclosing the palea and flower, the awn more or less straight or flexuose, $2-3.5 \mathrm{~cm}$ long, slightly twisted in the lower part, minutely scabrous, inconspicuously articulate with the lemma but not dilated at the base and rather tardily deciduous, the callus shortly oblique, shorter than the diameter of the body of the lemma, obtuse or minutcly pointed, bearing white, erectly divergent unequal hairs up to 1.5 mm long. Palea thinly hyaline, elliptical to oblong, obtuse or the apex more or less irregular, nerveless, glabrous, c. onc-half to one-third as long as the lcmma. Lodicules 2 , very thinly hyaline, obtriangular and truncate, or more or less oblanceolate and irrcgular, glabrous, nerveless, c. $0.25-0.75 \mathrm{~mm}$ long. Stamens $2-3$ with only 1 anther fully devcloped in all spccimens examined and another 1 (or 2) abortive. Caryopsis obovoid, turgid, lightly compressed, c. $1.2-1.5 \mathrm{~mm}$ long and c. 0.5 mm in diameter, brown, the hilum linear, straight, inconspicuous, c. two-thirds as long as the grain, the scutellum broad, almost half as long as the grain. "Serrated Tussock", "Yass Tussock".

#### Abstract

Specimens Examined: South Coast: Bega River, Hindle NSW 115765, 11.1965. Northern Tablelands: Rockvale via Armidale, Green NSW 115767, 10.1955. Central Tablelands: Orange, Madsen NSW 5J322, 2.1948; Blayney, Shire Clerk NSW 3109, 3.1947; Neville via Blayney, Radburn NSW 115766, 1.1949; Moss Vale, Rodway NSW' $89844,7.1937$; 4 miles [7 km] N. of Berrima, Green NSW 115775, 6.1950; Carcoar, Charles NSW 115770, 12.1948; Rockley, Cobb NSW 115760, 12.1948; Oberon district, Cantrill NSW 2264, 11.1946. Southern Tablelands: Gibraltar Creek arca, Paddys River district, Pullen 3708A, 3708B (NSW), 11.1962; "Murray Flats", Goulburn, Fizzerald NSW 115768, 11.1946 and NSW 4743, 12.1947; Gunning, Shire Clerk NSW 51321, 12.1943; Yass, Shire Clerk NSW II5759, 2.1936, NSW 115762, 115764, 11.1936; Yass, Dunlop NSW 89840, 10.1939: Yass, Sleeman NSW 115774. Central Western Slopes: Mudgee district, Sengelman NSW 115773, 11.1962.

In South Ameriea this grass is reported to be eaten by eattle, but in Australia it is neglected by stock, tends to over-run pasturcs and seriously reduces the valuc of infested propertics. Its panicles, bearing minutc seeds, arc casily detached from the tussock, lifted by even the lightest breeze, and may be carried scveral kilometres by wind. Any tussock permitted to fruit may thus infect properties over a considerablc radius from the source. It is therefore rcgarded as a serious noxious weed especially in Tablelands districts where it appears to thrive best. Control measures have received cxtensive study by agronomists.

## PIPTOCHAETIUM Presl

P. stipoides (Trin. et Rupr.) Hack. ex Arech. has been eultivated experimentally at the Botanic Gardens from seed from Uruguay [Vickery NSW 115730, 11.1953].
P. bicolor (Vahl) Desv. has been cultivated experimentally by the CSIRO at Ginninderra, Canberra (A.C.T.) [Strong NSW 115731, 115732, 11.1962].
